(54) IgG Preparations

(57) There is disclosed an immune gammaglobulin (IgG) preparation for the treatment and prevention of rheumatoid arthritis. The treatment involves passive immunization against a mixed spectrum of infectious bacteria which reside in the human gastrointestinal tract. The passive immunization may be accomplished

by oral ingestion of IgG immunoglobulin obtained from the milk of cows that have been immunized against a specific spectrum of bacterial types. A unique combination of bacterial species is formulated into a vaccine which may then be used to immunize dairy cattle. Preferably, the IgG preparation is obtained from the milk of the immunized cows.

SPECIFICATION

An Immune Gammaglobulin Preparation for the Treatment of Rheumatoid Arthritis

A number of years ago it was commonly believed that rheumatoid arthritis had an infectious etiology. This view is not popular today, although the inflammatory features and constitutional manifestations of rheumatoid arthritis—the synovitis and granulomatous lesions, the fever, tachycardia, leukocytosis, lymphadenopathyl and occasional spelnomegaly, the accelerated erythrocyte sedimentation rate and other changes in "acute phases reactants"—are all compatible with an infectious process. Competent and repeated bacteriologic studies have failed to recover consistently a single infectious agent from the blood, synovial fluid, synovial tissues or subcutaneous modules. 10 Attempts to transmit the disease by injecting joint fluid from patients with rheumatoid arthritis into the 10 joints of other human subjects have been unsuccessful. Subcutaneous modules have failed to survive following homologous transplantation (Bauer, et. al., 1951).

An infectious process may appear to precipitate the onset of rheumatoid arthritis in a sufficient number of patients, and may exert a deleterious influence on the course of the disease when it has 15 already been established. There is statistical evidence to support this clinical impression (Lewis-Faning, 1950).

Many attempts have been made to produce a disease in animals similar to rheumatoid arthritis. While a variety of bacteria can produce arthritis in animals, they fail to reproduce the clinical and pathologic features of rheumatoid arthritis, particularly the self-perpetuating characters of the proliferative arthritis. Arthritis bearing some semblance to the human disease has been produced in mice by pleuro-pneumonia-like organisms (Sabin, 1939) and in swine by Erysipelothrix rhusiopathiae (Sikes, et al, 1955). The concept that these organisms may initiate a hypersensitivity mechanism has been postulated (Sikes, et al), 1955).

Students of rheumatoid arthritis nevertheless continue to be intrigued by certain recurring 25 themes that suggest relationships between infections and joint diseases. Gonorrhea, for instance, is capable not only of producing typical gonorrheal arthritis but also of occasionally introducing chronic arthritis which evolved into typical rheumatoid arthritis. No statistics are available on the incidence with which this occurs, so one cannot know how much to stress the relationship. Tonsilitis or pharyngitis may also be followed by a polyarthritis, which at first appears to be rheumatic fever but which evolves 30 into rheumatoid arthritis. Acute viral infections, especially rubella in young women, may be followed by persistent polyarthritides involving small joints as well as large; these arthritides generally run a several-month course of persisting joint disease resembling rheumatoid arthritis before gradually subsiding.

While chronic infection by an unknown agent remains a popular assumption for the etiology of 35 rheumatoid arthritis, no published data exist to support the presumption. Some students of the disease suspect that if infection is a factor it may not be infection by any specific type of microorganism, but rather infection by a wide variety of banal microorganisms with an altered host response generated by the infections responsible for the disease. The present invention is based on this theory for the origin of rheumatoid arthritis.

Although the infectious etiology has never been established, several recent developments appear 40 relevant in support of this theory. Some of these are as follows:

1. Patients with rheumatoid arthritis have lower than normal levels of IgA, the class of immunoglobulin found in secretions of the gastrointestinal tract.

2. Immunoglobulin A produced in response to immunization via the salivary glands is found in serum colostrum and milk as well as in the saliva. It is suggested that the IgA is transported to these various fluids via the gastrointestinal tract and the lymphatic system (Michelok, et al, 1975).

3. Following an intestinal bypass operation for morbid obesity, certain patients develop symptoms that are virtually identical with rheumatoid arthritis. The onset of arthritis is accompanied by the appearance in blood serum of circulating cryoproteins composed of IgG, IgM, IgA, complement 50 components C3, C4, C5, and IgG antibody against E. coli and B. fragilis. Removal of the intestinal bypass results in complete remission of the symptoms (Woods, et al, 1976).

4. A type of Diplostreptococcus agalactiae belonging to the streptococci group B has been implicat das an etiologic agent inrheumatoid arthritis (Svartz, 1972). This streptococcus is present in most commercially available pasteurized milk but not in immune milk.

5. A predisposition to rheumatic disease appears to be inherited via the histocompatibility antigens (HL---A). These antigens probably determine host response to infective agents.

On the basis of this evidence, it is concluded that rheumatoid arthritis has an infectious origin; the side of infection occurs in the gut; a number of different bacterial strains are involved in the infection; the infection probably results because of a failure in the host's immune defense mechanism; and the most effective way to treat the disease is to reestablish the immune protection against the infectious agent in the gut.

Treatment of Infection

There are basically two methods which may be used for the treatment of infection: the immune approach which involves either active or passive immunization against the infectious pathogens, and the use of antibiotics such as penicillin, tetracycline, ampicillin and the like. Antibiotics are not specific in their activity, and they kill a wide spectrum of beneficial as well as harmful bacteria. On the other hand, the immune approach is highly specific. Bactericidal antibodies produced against a specific strain of bacteria react only with that strain and have no harmful effects on other types of bacteria. Moreover, antibodies, unlike antibiotics, are natural body products and have no known side effects. Since the objective of the invention is to control infection by a specific group of bacteria, without harming beneficial bacteria in the gut, the immune approach is the method of choice.

Active and Passive Immunization

There are two different methods to achieve immune protection. Active immunization is a process whereby the host is actively immunized with a vaccine which stimulates the immune system of the host to produce protective antibodies against factors contained in the vaccine. Active immunization occurs under natural conditions when the host is exposed to infectious pathogens. Passive immunization is a process whereby antibodies obtained from one individual who has been actively immunized are given to a second individual. By this process, the protective antibodies are transferred from the immune host to the recipient. Passive immune protection is temporary and lasts only as long. as the passively acquired antibodies persist in the system of the recipient. For example, antibodies 20 collected from horses immunized against tetanus toxic can be given to humans infected with tetanus in 20 order to obtain temporary immune protection against the toxin produced by tetanus bacteria.

In a previous patent; (U.S. Patent No. 3,626,057) there is described a process for producing tetanus antitoxin in milk. This patent teaches that the cow can be actively immunized against tetanus toxin; that antibodies produced by the cow against the toxin can be obtained from the cow's milk; and 25 that these antibodies can be used to treat animals infected with the tetanus bacteria in such a manner. that the antibodies neutralize the toxin. The patent teaches that the passively administered antibodies neutralize the life-threatening toxin produced by the bacteria, thereby, providing temporary immunity against the toxin.

Passive immunization differs from active immunization in that the immune protection is 30 temporary and lasts only as long as the protective antibodies are present. Active immunization is more 30 permanent because the immune system of the host continues to produce protective antibodies in the presence of the stimulating antigen.

Recent studies in the field of gut immunology have shown the existence of a local immune mechanism in the gut. This immune system of the gut produces a special type of antibody which 35 functions to control bacterial infestations in the lumen of the gut. The antibody called secretory. immunoglobulin or IgA is produced in response to the local active immunization of the gut mucosa by the antigen. The secretory immune system of the gut functions to prevent the colonization and proliferation of harmful bacterial species in this environment. It is believed failure of the local immune system of the gut allows unknown harmful bacteria to become established and that this bacteria 40 causes rheumatoid arthritis. According to this theory, rheumatoid arthritis results from a failure of the local immune system of the gut to produce and secrete protective antibodies against harmful bacteria... Thus, the inability of the host to respond to active immunization precludes this method as an approach, to the treatment of rheumatoid arthritis.

., The present invention describes an immune gammaglobulin (IgG) preparation for use in controlling the growth and proliferation of harmful bacterial pathogens--specifically, in the environment of the gastrointestinal tract of man; the method being that of passive immunisation by oral ingestion of protective antibodies produced in the cow. The method provides temporary immune protection which is highly specific for those species of bacteria used to produce the antibodies and does no harm to the normal beneficial bacteria that reside in the gut. The antibodies used in this 50 method preferably constitute the preparation of this invention.

Cow,'s milk provides the preferred source of the immune gamma-globulin preparation of the invention. It is very specific in that it defines a unique population of antibodies in milk (IgG type) that react with a known spectrum of bacteria and this reaction results in the beneficial effect, which is treatment and prevention of rheumatoid arthritis.

The type of immunoglobulin is an important consideration with regard to patentability of this invention because there are five known classes of immunoglobulin which are designated IgG, IgM, IgA, IgD, and IgE (Nisonoff, et al, 1971. Each type of immunoglobulin differs structurally (Waldman et al, 1970), and has a different biological function within the body (Waldman, et al, 1971 and Franklin, 1964). Moreover, there are striking variations in the locations of immunoglobulins within the body. For example; distribution clearly distinguishes immunoglobulin classes IgA and IgG. The most striking feature of IgA is its high concentration in external secretions of the body including the gastrointestinal fluid. It has been clearly shown that the immune system which contributes IgA to gastrointestinal fluid is a separate and distinct system from that which produces IgG.

In the human, IgG occurs primarily in the vascular and intracellular spaces of the body (Waldman

55

10

30

et al, 1970), and very little IgG finds its way into the gastrointestinal fluids. Another important difference between the classes of immunoglobulin is related to their metabolic rate. The degradation of each class of immunoglobulin, regardless of its location within the body, appears to be under a parate control. The functional catabolic rate varies from as low as 6.5% for IgG to as high as 90% for IgE with other classes of immunoglobulin falling in between (Waldman et al, 1970). Further, the different immunoglobulin classes also differ in their avidity with which they bind to antigens, and in their ability to combine with complement, which is one of the requisites for killing living bacterial cells (Heremans, 1960). It is important to emphasize these differences in the types of antibodies because immune effects may vary depending on the type of antibody involved.

The most commonly held theory is that the different classes of immunoglobulin have evolved to function in different environments within the body. It is known, for example, that a special and distinct immune system exists for the production of antibodies which function in the environment of the gut. Moreover, there is general agreement that the immune functions of the gut are controlled specifically by IgA antibodies and not IgG. Therefore, under natural conditions, IgA is the class of immunoglobulin which regulates immune control over bacterial infections which occur in the gastrointestinal cavity of man. Since IgG, IgM, IgD, and IgE are not normally found in the intestinal secretions, it is not logical to expect that any of these types of antibodies would be effective in treating infections in the environment of the gut.

The principal immunoglobulin in the milk of cows is IgG, not IgA (Sullivan, et al. 1969). Therefore, 20 bovine milk is not an obvious source of antibody for treating bacterial infections of the gut in man because of its high concentrations of IgG and low concentrations of IgA.

The method of immunization is another important parameter when considering the different classes of immunoglobulin. It is well known to those skilled in the art that different methods of immunization result in the preferential production of different types of entibodies. For example, local immunization of secretory tissues achieved by exposing the tissue of antipodies stimulates the preferential production and secretion of IgA type immunoglobulins. The technique of intramammary perfusion as described in the Petersen patent (U.S. Patent 3,376,198) is an example of local immunization. This method stimulates production and secretion of IgA antibodies and is not an effective method for producing IgG.

To produce the preparation of the present invention, intramuscular injection is preferably used, because IgG is the principal immunoglobulin in cow's milk, not IgA, and in the cow, systemic immunization is the preferred method for generating IgG type antibodies in milk. This distinction between the IGG and IGA type immunoglobulin is important because it teaches that systemic immunization and not local immunization is the preferred method for obtaining milk antibodies of high itier. Moreover, this distinction teaches that the immune products produced by mammary perfusion of a vaccine are distinctly different from the immune product produced by intramuscular injection of the identical vaccine. Thus, the product of this invention (IgG antibodies) is distinctly different from the product obtained by the Petersen process.

The immune product of this invention is an improvement over the product of Petersen's invention 40 because the concentration of antibodies of the IgG type is significantly higher than the concentration of antibodies of the IgA type. There is no evidence in the literature to support the claim that IgG antibodies can be produced by intramammary perfusion of antigens. Moreover, since the levels of IgA immunoglobulins are either non-extant or extremely low in cow's milk, it is unreasonable to suggest that the teaching of Petersen's patent has any relevance to the claim of this invention. On the contrary, the teaching of the Petersen patent leads away from the discovery of this invention since it implies that IgA is a biologically active factor in cow's milk, which has potential therapeutic application.

Thus, the preparation of the present invention is preferably obtained by formulating a unique combination of bacterial species into a vaccine, which is administered to healthy dairy cows. The IgG antibodies obtained from the milk of the immunized cows constitute the preparation of the invention which may be used in the method of treatment involving the passive immunization of the patient by oral ingestion of the IgG immunoglobulin. This passively immunizes against a mixed spectrum of infectious bacteria which reside in the gastro-intestinal tract. This treatment eliminates conditions in the gastro-intestinal tract which cause rheumatoid arthritis.

The invention will now be described with reference to the accompanying drawings, in which:

which ensures authenticity of bacterial strains and the highest standard of purity that is available. Upon receipt, each individual bacterial strain was grown on a blood agar plate to test the viability of the culture and to determine if growth pattern is typical or atypical of the bacteria in question. A single colony from each of the test cultures was taken for histological examination to further ensure authenticity and plurality of the culture. A single colony of each culture was used to inoculate 500 ml of standard culture broth. The standard broths recommended by the American Type Culture Collection were used to grow each of the specific bacteria listed in Table 1.

All organisms were incubated as static cultures with the exception of 12, 13, 14 and 60, which were incubated in the shaker to provide agitation. Identification of bacterial strains and the American Type Culture Collection catalog numbers are shown in Table 1. Each culture was cultivated for 48 hours at 37°C. Following incubation, the cultures were killed by heating at 60°C for two hours. Samples of the killed bacteria were used to inoculate fresh broth which was then incubated for 24 hours at 37°C to determine if the killing process was complete. Only cultures proven sterile by this procedure were used for further processing. Sterile cultures were then washed five times in distilled water and the cells were recovered by centrifugation. The bacterial cells were frozen by immersion in liquid nitrogen and freeze-dried by the process of lyophilization. The lyophilized cells were stored in sterile vials until used for production of the polyvalent vaccine. The polyvalent vaccine was prepared by weighing out one gram quantities of each of the bacterial strains. The dry cells were mixed together and this mixture was suspended in sterile physiological saline (20 grams of bacteria per 500 ml saline).

A sample of the concentrated solution was diluted in serial fashion with saline to determine dilution which gives a concentration of 4x108 ml per cc. The stock concentrated polyvalent vaccine was dispersed into multiple containers and stored frozen. A sufficient amount of concentrated antigen was included in each individual container to immunize 50 cows. The final dilution of concentrate was made just prior to immunization. The preferred procedure is to remove a sufficient number of vials to immunize the number of cows to be treated. For example, the vials are removed 24 hours prior to the planned time of immunization; a sample of the concentrate is then diluted in a sterile container to a final concentration of 4×108 cells per ml. The maximum response in cows is obtained by injecting 20×108 bacterial cells or 5 cc of the sterile preparation which is 4×108 cells per ml according to the method of immunization described below.

30 Preferred Process for Immunization of Cows

The antibody product of the invention is produced by immunizing cows with the polyvalent antigen prepared as described above. The cows are injected with 5 cc of polyvalent antigen containing 20×108 bacterial cells. The injection is made intramuscularly in the gluteus maximus muscle of the hind leg. This procedure is repeated at one week intervals for four consecutive weeks beginning 2-3 weeks prior to the predicted day of parturition. Following the primary immunization, booster injections using the same concentration of the antigen, are given every 14 days. This method of immunization gives the maximum antibody titer.

Preferred Collection, Handling and Processing of Milk

The milk is collected from immunized cows in a modern dairy parlor. A fully automated milking system collects and stores the milk under complete sanitary conditions. The milking system consists of automated machines connected directly to refrigerated storage tanks by a closed system of pipes. The complete system is cleaned and sterilized following each milking to ensure maximum sanitary conditions. It is important to take careful steps to prevent the growth of bacteria to immune milk during processing, since such bacteria can lower the titer of antibodies in the milk.

Milk is transported daily from the refrigerated holding tanks to a dairy processing plant by milk transport trucks. At the dairy plant a high temperature short-time system is used to pasteurize the antibacterial milk. Specialized dairy machinery provides the flash heating of a continuous flow of milk to 155°F for a period of not more than 15 seconds. Temperature and time is critical since antibody is susceptible to degradation by heat. Milk antibody is destroyed at temperatures above 165°F, if held for 50 periods longer than one minute. Following pasteurization, the whole milk is immediately cooled and the 50 fat is removed by centrifugation, and the skimmed whole aftibacterial milk is powdered by a spray process. The spray process consists of a large drying chamber into which not air (350°F) is blown at high velocity. The skimmed milk is atomized into the chamber where the finely divided milk particles are instantly dried as they fall to the bottom of the tank. The dried milk is removed automatically by 55 means of mechanical devices and the milk powder is packaged under sanitary conditions. Prior to 55 atomizing, the skimmed milk is condensed by boiling in a chamber under vacuum (100-110°F). At each step it is critical to keep the bacteria from contaminating the milk since this reduces the titer of the antibody. W. S. att S. S. Car Second

Preferred Testing Procedures

Immune milk was prepared in inbred Holstein cows. The cows were immunized by the intramuscular injection of a mixture of bacterial antigens identified in Table 1. The vaccine was prepared by the process described above. The immunologic response of the cows was boosted by bi-

weekly injections of the vaccine. The milk from these cows was pooled, the fat removed, and the nonfat milk was pasteurized by exposure to 160°F for 16 seconds followed by a spray-drying process in which the t imperature of the milk did not exceed 85°F. The milk was packaged in one quart polyethylen containers. Control milk (placebo) was non-fat powdered milk purchased from a local 5 producer. Erythrocyte sedimentation rates were determined on freshly collected blood by the method of Westergren and corrected for hematocrit according to the method of Wintrope & Langsberg (1935). Rheumatoid factor titers were determined by the Singer-Plotz (1966) macroscopic tube test. Patients were accepted for the study on the basis of an elevated erythrocyte sedimentation rate 10 10 and a positive rheumatoid factor titer. Nine patients were studied for 12 months and 11 patients were studied 18 months. The patient group was composed of thirteen caucasian females ranging in age from 32 to 69 years with an average of 50.4 years, and seven caucasian males ranging in age from 43 to 70 years with an average age of 58.1 years. The mean duration of arthritis was 10.8 years for the females and 11.0 for the males. Patients were randomly placed either on immune milk or on non-15 immune milk (a commercial product purchased in the Dayton area that served as a placebo). Both milk products were packaged in identical containers and were identified as being immune milk or placebo, respectively, by a blue or red pressure-sensitive label that was attached to each container at the time it was filled. The labels were removed just prior to dispensing the milk to the patients. Thus, at no time did the patients know whether they were receiving immune milk or placebo. Patients were randomly 20 20 (as determined by the flip of a coin) selected to receive either immune milk or the placebo during the first six-month period. At the end of this time, those that were receiving immune milk were placed on the placebo and those that were receiving placebo were placed on immune milk for the second sixmonth period. At the end of the second six-month period, 11 patients volunteered to remain on the study for an 25 25 additional six months. The type of milk (immune or placebo) was again changed at this time and observations were continued. Thus, the study was comprised of three six-month periods, 11 of the patients participating for three periods and nine participating for two periods. Patients were seen at monthly intervals at which time a one month supply of milk was dispensed, an evaluation questionnaire was filled out and a blood sample was collected for rheumatoid . 30 30 factor titer, erythrocyte sedimentation rate and hematocrit determination. Patients were instructed to take a quantity of non-fat milk solids equivalent to one quart of milk post prandially two times daily. The milk solids were freshly dissolved in one pint of cool tap water kill immediately before ingestion shortly after awakening in the morning and again just prior to retiring at night. They were told to see their physician as usual and to follow the treatment regimens prescribed 35 35 by him. Medication was to be taken ad libitum or as prescribed by their regular doctor. We requested monly that they report the quantity of medicines taken. A questionnaire was completed by each patient at monthly intervals. It was divided into six sections that deal with: 1) duration of morning stiffness, 40 2) severity of pain experienced in each of eight joints, "3) type and quantity of drugs with short-term actions that were taken, 4) type and quantity of drugs with long-lasting actions that were taken, 5) ability of patient to conduct his normal activities, and 45 6) severity of symptoms of rheumatoid arthritis. 45 The numbers shown in the spaces next to each answer indicate the score assigned to that answer in the course of evaluating the questionnaires. In scoring the sections dealing with medications, an effort was made to reflect the relative anti-inflammatory and analgesic activities of the various drugs used. A five-grain aspirin tablet was assigned a value of one. All other drugs (with the exception of gold,

The numbers shown in the spaces next to each answer indicate the score assigned to that answer in the course of evaluating the questionnaires. In scoring the sections dealing with medications, an effort was made to reflect the relative anti-inflammatory and analgesic activities of the various drugs used. A five-grain aspirin tablet was assigned a value of one. All other drugs (with the exception of gold, plaquenil and cortisone shots which were considered separately) were arbitrarily assigned values relative 50 to aspirin. Thus, all salicylate preparations, Tylenol, Darvon, Motrin, etc. were considered equivalent to a five-grain aspirin tablet and were also assigned a value of one. The numbering of Prednisone was multiplied times four, the number of Indocin capsules taken was multiplied times 2.5. The number of grains of codeline was multiplied times two, and the number of Butazoladin tablets taken was multiplied times seven.

The mean scores in each category were calculated for each six-month period. The differences of the means were then calculated by subtracting the mean values scored during administration of immune milk from those scored during administration of placebo. When the results were calculated in this manner, improvement in the patient's condition during the period he received immune milk was indicated by negative values for questions one and six, and by positive values for all other questions. Mean corrected erythrocyte sedimentation rates (ESR) and rheumatoid factor titers (RF) were respectively shown in a similar manner. These were calculated in such a way that positive values reflect a lower erythrocyte sedimentation rate or rheumatoid factor titer during administration of immune milk. The data were statistically evaluated using the Statistical Analysis System of Goodnight.

et al. (SAS institute, Raleigh, N. C.). Calculations were performed with the aid of an IBM model 370/155 computer.

Results

The immune milk was well tolerated by all patients with the exception of one who had pernicious anemia. This patient complained of diarrhea and was terminated from the study. Some patients reported a weight gain during the course of the study. This may have been due to the increased caloric intake from the milk or possibly reflects a generalized improvement in their physical condition.

^{*}Coefficient of variation.

As shown in Table 3, patients were observed during a total of 27 control periods (six-month) periods during which they received placebo) and 24 test periods (six-month periods during which they received immune milk). One patient had sustained a physical injury to one of his ankles and feet. The pain in these joints was not evaluated, which accounts for there being a smaller number of periods of evaluation for these joints. The erythrocyte sedimentation rates for one patient were so extremely abnormal (more than two standard deviations removed from the mean of the values for the other patients) that they were not included. This omission accounts for the smaller number of observations reported for that variable.

The mean values and coefficients of variation (C. V.) are listed in the table to reach variable. Differences between the means were calculated by substracting the mean value obtained during the periods the patients received immune milk from that obtained during the periods they received the placebo. A favorable response to immune milk is indicated by negative values for AM stiffness (question 1) and Monthly change (questions 6a, b, and c) and by positive values for all other variables, An effective response to immune milk was obtained for all data obtained from the questionnaires. Probabilities (P) indicate a high degree of statistical significance in every instance. The small mean differences obtained for erythrocyte sedimentation rate and rheumatoid factor titer were not significant. When erythrocyte sedimentation rates were considered on an individual basis, however, four of the twenty patients studied had statistically significant decreases while receiving immune milk.

Although immune milk had no significant effect on the mean values for rheumatoid factor titer, examination of individual patients revealed some interesting responses. Seven of the twenty patients studied had negative rheumatoid factor tit is on at least one occasion during the period they were receiving immune milk. Four of them became negative during the period that they received immune milk and their titers falled to become positive during the following six-month period when they received the control (placebo) milk as shown in Figure 2. Continuation of the study past this reporting period reveals that 13 of 25 patients lost the rheumatoid factor from their blood.

Discussion to the control of the first of the first of the first of the same of the same of the first of the

The scientist in charge of this study personally interviewed each patient at monthly intervals, and

40

15

recorded their answers to the questions. Every effort was made not to influence the patient's answers. The patients were initially informed and were frequently reminded that, during certain periods of the study, they would receive a placebo. It was anticipated that this knowledge would serve as an inducement for the patients to answer the questions objectively and without bias. At no time were the patients informed whether they were receiving immune milk or the placebo. The question regarding medication taken "yesterday" (question #3) and the question regarding

gold shots, Plaquenil and cortisone, shots (question #4) are objective and are of primary importance in considering answers given to the other questions. These questions are important for two reasons:

1) if the immune milk is effective in relieving symptoms of the disease, the patient would be 10 expected to take fewer medicines that were allowed ad libitum. On an average, patients reported that they took four less aspirins or their equivalent per day during the periods that they received immune milk. They also reported that they received fewer gold shots, Plaquenil and cortisone shots during these periods: and

2) if patients took smaller quantities of analgesics and other medicines useful in the treatment of rheumatoid arthritis, one would expect them to report increased discomfort unless the immune milk was influencing the disease favourably. As noted in Table 2, significantly less joint involvement was reported during periods that the patients received immune milk even through they were taking less medicines for their arthritis.

Patients started on the study at monthly intervals over a one-year period, and the type of milk product (immune milk or placebo) that they initially received was randomized. The observation that positive responses or improvement were obtained for all parameters of the questionnaire, and that these mean responses were statistically significant strongly indicate that immune milk had a beneficial effect on the patients. This conclusion is reinforced by the observation that 20% of the patients experiences a statistically significant (p<0.05) decrease in erythrocyte sedimentation rate while

Results of the rheumatoid factor titers are difficult to evaluate. This is due to at least in part to the fact that the origin and role of rheumatoid factors in the etiology and prognosis of rheumatoid arthritis is not understood. Rose et al (1948) showed that sheep red blood cells that were sensitized with rabbit antibody underwent agglutination in the presence of blood serum from patients with rheumatoid 30 arthritis. The test depends on the specific reaction between normal immunoglobulin (either rabbit or human IgG) with rheumatoid factors. The specificities exhibited by rheumatoid factor are like those that would be expected of antibody against IgG (Epstein et al, 1956). The presence of rheumatoid factors has been correlated with disease severity in rheumatoid arthritis and can be identified in proteins 35 35 precipitated in the tissues of patients with rheumatoid arthritis. Although a small percentage of patients with rheumatoid arthirits do not have positive rheumatoid factor titers, it is generally agreed by most rheumatologists that positive agglutination reactions do not revert to negative even when the disease is in remission. De Forest et al (1958), however, described a small number of patients who had positive rheumatoid factor titers that reverted to negative following a remission. When recrudesence of 40 the disease occurred, the test again became positive. Aho, et al (1959) noted, however, that most 40 patients whose disease had become inactive remained serologically positive. The fact that negative titers were observed in 60% of our patients and that in half of these, the titers remained negative for six months, proves that immune milk is affecting a primary etiologic factor responsible for rheumatoid

The effect of immune milk in alleviating the symptoms of rheumatoid arthritis is particularly relevant when considered on the basis of the recently described relationship between the histocompatibility antigens (HL—A) and the susceptibility to rheumatic disease (Brewerton, 1976). Histocompatibility antigens are genetically determined antigens that are found on all human cells. The genes controlling their inheritance are called histocompatibility genes. There are now 50 known to be over 40 of these genetically determined antigens. They are responsible for rejection of tissue grafts made between individuals other than identical twins. Superficially the HL-A antigens resemble ABO blood groups in that they are inherited for a lifetime. Their functions is not yet known, except in the highly artificial situation produced by transplantation. It is known, however, that the histocompatibility genes are closely linked with the immune response genes on the sixth chromosome. 55 In this relationship, they may determine the immune response of the individual to a foreign invader, such as a bacteria.

Persons with HLA—B27 appear to be particularly susceptible to a variety of rheumatic diseases. It is postulated that this histocompatibility antigen dictates a type of immune response which in the presence of other predisposing factors leads to rheumatoid arthritis. After an intestinal inf ction with 60 yersinia enterocolitica, some patients develop an acute peripheral arthritis (Ahvonon, et al, 1969). Similarly, after salmonella infection, about 2% of patients develop acute peripheral arthritis (Warren, 1970). HLA—B27 was found in 43 of 49 patients with yersinia arthritis and in 15 of 16 with salmonella arthritis (Aho, 1974). It is an attractive possibility that infective agents may thrive in the intestinal tract without giving rise to local symptoms. In patients with HLA—B27, a host response is established that results in arthritis. Thus, it is not necessary for the infective agent to gain entry into the

1	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin, said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. An'immune gammaglobulin preparation according to any one of claims 1 to 4, said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two or more of the American Type Culture Collection bacterial antigens including:	35
1	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin, said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. An'immune gammaglobulin preparation according to any one of claims 1 to 4, said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two or more of the American Type Culture Collection bacterial antigens including: Staphylococcus aureus	35
40	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin, said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. An'immune gammaglobulin preparation according to any one of claims 1 to 4, said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two or more of the American Type Culture Collection bacterial antigens including: Staphylococcus aureus 11631 Staphylococcus epidermidis	35
1	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin, said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. An'immune gammaglobulin preparation according to any one of claims 1 to 4, said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two or more of the American Type Culture Collection bacterial antigens including: Staphylococcus aureus 11631 Staphylococcus epidermidis	35
40	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin, said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. An'immune gammaglobulin preparation according to any one of claims 1 to 4, said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two or more of the American Type Culture Collection bacterial antigens including: Staphylococcus aureus Staphylococcus epidermidis Streptococcus pyogenes, A. Type 1 Streptococcus pyogenes, A. Type 3	35
40	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin, said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. An'immune gammaglobulin preparation according to any one of claims 1 to 4, said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two or more of the American Type Culture Collection bacterial antigens including: Staphylococcus aureus Staphylococcus pyogenes, A. Type 1 Streptococcus pyogenes, A. Type 3	35
40	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin, said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. An'immune gammaglobulin preparation according to any one of claims 1 to 4, said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two or more of the American Type Culture Collection bacterial antigens including: Staphylococcus aureus Staphylococcus pyogenes, A. Type 1 Streptococcus pyogenes, A. Type 3 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 5	35 *** 40
40	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin, said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. An'immune gammaglobulin preparation according to any one of claims 1 to 4, said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two or more of the American Type Culture Collection bacterial antigens including: Staphylococcus aureus Staphylococcus pyogenes, A. Type 1 Streptococcus pyogenes, A. Type 3 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 5	35 *** 40
40	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin, said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. An'immune gammaglobulin preparation according to any one of claims 1 to 4, said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two or more of the American Type Culture Collection bacterial antigens including: Staphylococcus aureus Staphylococcus pyogenes, A. Type 1 Streptococcus pyogenes, A. Type 3 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 8 Streptococcus pyogenes, Type 12	35 *** 40
40	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin, said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. An'immune gammaglobulin preparation according to any one of claims 1 to 4, said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two or more of the American Type Culture Collection bacterial antigens including: Staphylococcus aureus Staphylococcus pyogenes, A. Type 1 Streptococcus pyogenes, A. Type 3 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 14	35 40 45
40	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin; said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. An'immune gammaglobulin preparation according to any one of claims 1 to 4, said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two or more of the American Type Culture Collection bacterial antigens including: Staphylococcus aureus Staphylococcus epidermidis Streptococcus pyogenes, A Type 1 Streptococcus pyogenes, A Type 3 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 14 Streptococcus pyogenes Type 18	35 40 45
40	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin, said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. 'An immune gammaglobulin preparation according to any one of claims 1 to 4, said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two or more of the American Type Culture Collection bacterial antigens including: Staphylococcus aureus Staphylococcus epidermidis Staphylococcus pyogenes, A. Type 1 Streptococcus pyogenes, A. Type 3 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 14 Streptococcus pyogenes, Type 18 Streptococcus pyogenes Type 18	35 40 45
40	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin, said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. An immune gammaglobulin preparation according to any one of claims 1 to 4, said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two or more of the American Type Culture Collection bacterial antigens including: Staphylococcus aureus Staphylococcus epidermidis Streptococcus pyogenes, A. Type 1 Streptococcus pyogenes, A. Type 1 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 5 12347 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 14 Streptococcus pyogenes Type 18 Streptococcus pyogenes, Type 21 Streptococcus pyogenes, Type 22 Aerobacter aelogenes	35 40 45
40	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin, said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. 'An' immune gammaglobulin preparation according to any one of claims 1 to 4, 'said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two or more of the 'American Type Culture Collection bacterial antigens' including: Staphylococcus aureus Staphylococcus aureus 11631 Staphylococcus piogenes, A. Type 1 Streptococcus pyogenes, A. Type 1 Streptococcus pyogenes, Type 3 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 14 Streptococcus pyogenes, Type 14 Streptococcus pyogenes, Type 18 Streptococcus pyogenes, Type 18 Streptococcus pyogenes, Type 22 Aerobacter aerogenes Escherichia colf 26	35 40 45
40	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin, said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. 'An' immune gammaglobulin preparation according to any one of claims 1 to 4, 'said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two or more of the American Type Culture Collection bacterial antigens including: Staphylococcus aureus Staphylococcus progenes, A. Type 1 Streptococcus pyogenes, A. Type 1 Streptococcus pyogenes, Type 3 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 14 Streptococcus pyogenes, Type 14 Streptococcus pyogenes Type 18 Streptococcus pyogenes, Type 18 Streptococcus pyogenes, Type 22 Aerobacter aerogenes 10403 Aerobacter aerogenes 1267	35 40 45
40	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin, said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. An'immune gammaglobulin preparation according to any one of claims 1 to 4, said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two or more of the American Type Culture Collection bacterial antigens including: Staphylococcus aureus Staphylococcus epidermidis Streptococcus pyogenes, A Type 1 Streptococcus pyogenes, A Type 3 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 8 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 18 Streptococcus pyogenes, Type 18 Streptococcus pyogenes, Type 18 Streptococcus pyogenes, Type 18 Streptococcus pyogenes, Type 22 Aerobacter aerogenes Escherichia coli Salmonella enterltidis nesudomonas aeruginasa 7700	35 40 45
40 45 50	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin, said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. An'immune gammaglobulin preparation according to any one of claims 1 to 4, said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two or more of the American Type Culture Collection bacterial antigens including: Staphylococcus aureus Staphylococcus progenes, A. Type 1 Streptococcus pyogenes, A. Type 1 Streptococcus pyogenes, A. Type 3 Streptococcus pyogenes, Type 3 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 14 Streptococcus pyogenes, Type 18 Streptococcus pyogenes, Type 18 Streptococcus pyogenes, Type 22 Aerobacter aerogenes Escherichia coli Salmonella enteritidis pseudomonas aeruginosa Violeticula accuration	35 40 45
40	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin, said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. An immune gammaglobulin preparation according to any one of claims 1 to 4, said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two or more of the American Type Culture Collection bacterial antigens including: Staphylococcus aureus Staphylococcus epidermidis Streptococcus pyogenes, A. Type 1 Streptococcus pyogenes, A. Type 1 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 14 Streptococcus pyogenes, Type 18 Streptococcus pyogenes Type 18 Streptococcus pyogenes, Type 22 Aerobacter aerogenes Escherichia coli Salmonella enteritidis pseudomonas aeruginosa Klebsiella pneumoniae	35 40 45 50
40 45 50	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin, said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. An'immune gammaglobulin preparation according to any one of claims 1 to 4, said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two or more of the American Type Culture Collection bacterial antigens including: Staphylococcus aureus Staphylococcus epidermidis Staphylococcus pyogenes, A. Type 1 Streptococcus pyogenes, A. Type 3 Streptococcus pyogenes, Type 3 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 14 Streptococcus pyogenes, Type 14 Streptococcus pyogenes, Type 18 Streptococcus pyogenes, Type 18 Streptococcus pyogenes, Type 19 Streptococcus pyogenes, Type 22 Aerobacter aerogenes Escherichia coli Salmonella enterltidis pseudomonas aeruginosa Klebsiella pneumoniae Salmonella typhimurium	35 40 45 50
40 45 50	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin, said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. An immune gammaglobulin preparation according to any one of claims 1 to 4, said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two or more of the American Type Culture Collection bacterial antigens including: Staphylococcus aureus Staphylococcus epidermidis Staphylococcus progenes, A Type 1 Streptococcus pyogenes, A Type 1 Streptococcus pyogenes, Type 3 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 14 Streptococcus pyogenes, Type 18 Streptococcus pyogenes, Type 18 Streptococcus pyogenes, Type 22 Aerobacter aerogenes Escherichia coli Salmonella enteritidis pseudomonas aeruginosa Klebsiella pneumoniae Salmonella typhimurium Haemophilius influenzae	35 40 45 50
40 45 50	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin, said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. An immune gammaglobulin preparation according to any one of claims 1 to 4, said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two or more of the American Type Culture Collection bacterial antigens including: Staphylococcus aureus Staphylococcus progenes, A Type 1 Streptococcus pyogenes, A Type 1 Streptococcus pyogenes, A Type 3 Streptococcus pyogenes, Type 3 Streptococcus pyogenes, Type 8 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 14 Streptococcus pyogenes, Type 18 Streptococcus pyogenes Type 18 Streptococcus pyogenes, Type 19 Streptococcus pyogenes, Type 22 Aerobacter aerogenes Escherichia coli Salmonella enteritidis pseudomonas aeruginosa Klebsiella pneumoniae Salmonella typhimurium Haemophilus influenzae	35 40 45 50
40 45 50	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin, said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. An immune gammaglobulin preparation according to any one of claims 1 to 4, said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two or more of the American Type Culture Collection bacterial antigens including: Staphylococcus aureus Staphylococcus aureus Staphylococcus pyogenes, A. Type 1 Streptococcus pyogenes, A. Type 1 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 14 Streptococcus pyogenes, Type 18 Streptococcus pyogenes, Type 18 Streptococcus pyogenes Streptococcus pyogenes Type 18 Streptococcus pyogenes Streptococcus pyogenes Type 18 Streptococcus pyogenes Type 18 Streptococcus pyogenes Type 18 Streptococcus pyogenes Type 18 Streptococcus pyogenes Type 20 Aerobacter aerogenes Escherichia coli Salmonella enteritidis pseudomonas aeruginosa Klebsiella pneumoniae Salmonella typhimurium Haemophilus influenzae Streptococcus viridans Streptococcus viridans	35 40 45 50
40 45 50	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin; said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. An immune gammaglobulin preparation according to any one of claims 1 to 4, said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two or more of the American Type Culture Collection bacterial antigens including: Staphylococcus aureus Staphylococcus epidermidis Staphylococcus epidermidis Streptococcus pyogenes, A Type 1 Streptococcus pyogenes, A Type 1 Streptococcus pyogenes, Type 1 Streptococcus pyogenes, Type 8 Streptococcus pyogenes, Type 18 Streptococcus pyogenes, Type 22 Aerobacter aerogenes Escherichia coli Salmonella enteritidis pseudomonas aeruginosa Klebsiella pneumoniae Salmonella typhimurium Haemophilus influenzae Streptococcus viridans 13315 1422	35 40 45 50
40 45 50	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin, said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. An immune gammaglobulin preparation according to any one of claims 1 to 4; said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two or more of the American Type Culture Collection bacterial antigens including: Staphylococcus aureus Staphylococcus epidermidis Staphylococcus pyogenes, A Type 1 Streptococcus pyogenes, A Type 1 Streptococcus pyogenes, Type 3 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 8 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 14 Streptococcus pyogenes, Type 14 Streptococcus pyogenes, Type 18 Streptococcus pyogenes, Type 22 Aerobacter aerogenes Escherichia coli Salmonella enterludis pseudomonas aeruginosa Klebsiella pneumoniae Salmonella typhimurium Haemophilus influenzae Streptococcus viridans Proteus vulgaris Shigella dysenteriae	35 40 45 50 55
40 45 50	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin, said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. An immune gammaglobulin preparation according to any one of claims 1 to 4; said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two of more of the American Type Culture Collection bacterial antigens including: Staphylococcus epidermidis Staphylococcus epidermidis Streptococcus pyogenes, A. Type 1 Streptococcus pyogenes, A. Type 1 Streptococcus pyogenes, Type 3 Streptococcus pyogenes, Type 3 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 14 Streptococcus pyogenes, Type 14 Streptococcus pyogenes, Type 18 Streptococcus pyogenes, Type 18 Streptococcus pyogenes, Type 22 Aerobacter aerogenes Escherichia coli Salmonella enterltidis pseudomonas aeruginosa Klebsiella pneumoniae Salmonella typhimurium Haemophilus influenzae Streptococcus, Group B Streptococcus, Group B	35 40 45 50 55
40 45 50	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin, said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. An immune gammaglobulin preparation according to any one of claims 1 to 4; said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two of more of the American Type Culture Collection bacterial antigens including: Staphylococcus epidermidis Staphylococcus epidermidis Streptococcus pyogenes, A. Type 1 Streptococcus pyogenes, A. Type 1 Streptococcus pyogenes, Type 3 Streptococcus pyogenes, Type 3 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 14 Streptococcus pyogenes, Type 14 Streptococcus pyogenes, Type 18 Streptococcus pyogenes, Type 18 Streptococcus pyogenes, Type 22 Aerobacter aerogenes Escherichia coli Salmonella enterltidis pseudomonas aeruginosa Klebsiella pneumoniae Salmonella typhimurium Haemophilus influenzae Streptococcus, Group B Streptococcus, Group B	35 40 45 50 55
40 45 50 55	oral administration. 4. A preparation according to any one of claims 1 to 3, said preparation being for oral administration and being in a vehicle that is not harmful to the gammaglobulin, said vehicle helping to prevent destruction of the gammaglobulin in the gastrointestinal tract due to the action of proteolytic enzyme and changes in pH. 5. An immune gammaglobulin preparation according to any one of claims 1 to 4; said gammaglobulin having been produced by first preparing a vaccine from killed bacteria from two or more of the American Type Culture Collection bacterial antigens including: Staphylococcus aureus Staphylococcus epidermidis Staphylococcus pyogenes, A Type 1 Streptococcus pyogenes, A Type 1 Streptococcus pyogenes, Type 3 Streptococcus pyogenes, Type 5 Streptococcus pyogenes, Type 8 Streptococcus pyogenes, Type 12 Streptococcus pyogenes, Type 14 Streptococcus pyogenes, Type 14 Streptococcus pyogenes, Type 18 Streptococcus pyogenes, Type 22 Aerobacter aerogenes Escherichia coli Salmonella enterludis pseudomonas aeruginosa Klebsiella pneumoniae Salmonella typhimurium Haemophilus influenzae Streptococcus viridans Proteus vulgaris Shigella dysenteriae	35 40 45 50 55

10

injecting said vaccine intramuscularly in healthy cows once weekly for four consecutive weeks, and twice monthly thereafter, each injection involving 20×10^8 bacterial cells; collecting the milk from the immunized cows beginning the fourth week; and testing for titer to ensure that the minimum titer against each of the bacteria is 1—500, as determined by the tube agglutination method for testing antibody titer.

6. A preparation according to claim 5, wherein said vaccine has been prepared by a process which includes the steps of preparing cultures of bacterial strains in appropriate buffers, heat killing the bacteria, harvesting the killed bacteria by centrifugation, washing the bacterial strains, lyophilizing said washed strains, mixing the individual bacterial types on an equal weight basis, and suspending the mixed bacterial strains in a suitable vehicle for injection into cows to produce, in the milk system of the cows, an immune gammaglobulin (1gG).

7. A preparation according to claim 1 and substantially as hereinbefore described.

Printed for Her Majesty's Stationery Office by the Courier Press, Learnington Spa, 1979. Published by the Patent Office, 25 Southampton Buildings, London, WC2A 1AY, from which copies may be obtained.
